**AGC (Active Gain Control)**

**Stall Prevention**

Stable control is a basic operating requirement for motors used in printers, office appliances and industrial equipment etc. Because of their stable and precise controls, stepper motors are suitable for these applications. However, the highest priority of the stepper motor is to avoid stalls*1. Therefore, sufficient current margin is needed at all times to prevent sudden heavy torque changes and to achieve stable operation.

Reduction of the additional current for the torque margin is highly desirable for improving efficiency and suppressing heat generation. This requires complicated current adjustment by real-time monitoring of motor torque and current feedback, using additional sensors and microcontrollers. To solve these problems, Toshiba has developed the AGC architecture. AGC automatically optimizes the motor current depending on the torque needed. It prevents motors from stalling and provides the optimum efficient motor control that cannot be achieved by conventional motor control drivers.

**FEATURES**

- Drive current optimization
- Stall prevention

**ADVANTAGES**

- Optimized current control method for motor operation, i.e. current reduced to actual requirement
- Stable rotation and control

**BENEFITS**

- Significant heat reduction
- Efficiency increase
- Simplifying optimum current control system without microcontrollers, ADC, and sensors
- Noise reduction

**APPLICATIONS**

- Office appliances (printers and others)
- Industrial machines (vending machine, CNC machine, dispensing machine and others)
- Banking terminals (ATM, cash dispensers, etc.), Point-of-Sales

*1Stall: A stepping motor rotates synchronizing with pulses. However, its synchronization is lost when overload or a rapid speed change occurs, the motor stops but is still running at peak current. This phenomenon is called ‘Stall’.

**OPTIMIZE OPERATING CURRENT IN REAL-TIME**

System control difference between conventional and AGC architectures.

### Conventional

**Stepping Motor with open loop control**
A maximum constant current is required for a stable motor drive and to avoid step-out. Accordingly, at light load conditions the current efficiency is bad.

### AGC

AGC optimizes the motor current dynamically depending on the load torque. Efficient operation is realized by eliminating the additional current needed while keeping a minimum margin to operate efficiently.

### New approach with Active Gain Control

**Benefits**
- Current auto fitting / no step-out
- Power consumption reduced by up to 30%
- Chip temperature reduction by around 30°C

**Conventional**

**Open loop control**

For advanced control, MCU, ADC, and sensing element can be used for current optimization

**Motor current**

- Motor Drive Current (Constant current)
- Necessary current (Necessary torque)  
- Peak Torque

**Loss Current**

**Margin**

**New approach with Active Gain Control**

**Benefits**

- Current auto fitting / no step-out
- Power consumption reduced by up to 30%
- Chip temperature reduction by around 30°C

**AGC technology optimizes the motor drive current (auto fitting current)**

**Energy Saving (Less Heat Generation)**

**Motor current**

- Needed current (Variable)
- Needed current (Necessary torque)

**Torque control and motor operation current for stepper motors**

When some sort of loads are applied during motor rotation, load torque increases and its volume changes depending on the usage circumstances. Required current for the motor operation also changes by following the load change.

For advanced control, measurement against heat generation is necessary. Surpressing the torque margin, while securing its required value, is necessary. Both add complexity and cost to the system.

**Measurement against heat generation is unnecessary. Load from host control can be reduced**

### SIGNIFICANTLY REDUCTION OF SYSTEM POWER CONSUMPTION
